

Abstract

ADHD is treated as one condition, so ADHD tools are built one way. But children with ADHD differ enormously in **how** they focus, switch tasks, and stay motivated. **Attune** tests whether these differences form **measurable, stable cognitive profiles** — and whether matching teaching to a child's profile beats treating the condition as uniform.

Attune has two parts. A **profiling engine** measures four dimensions from behaviour alone — no labels, no clinical claims. A **learning game** then adapts to that profile: the student photographs any textbook page, an AI extracts the underlying concepts, and generates **brand-new** questions that become gates in a runner game.

Every app failed my sister. Her mother didn't — not through expertise, but through knowing exactly how one mind worked. Attune asks whether that knowledge can be measured, and given to every child for free.

- ### Background Research
- ADHD affects roughly **5–7% of children globally**; Indian estimates range **5–11%** of school-age children, with heavy underdiagnosis outside metros.
 - Existing tools assume a **single, averaged ADHD profile** — uniform timers, uniform rewards, uniform pacing.
 - Specialist support is highly personalised but costs **₹1,500–5,000 per session**, and a meaningful programme needs 20–40 sessions.
 - The gap:** the thing that actually works — deep knowledge of an individual child's mind — is exactly the thing that is unaffordable and unscalable.
 - No existing system **measures an individual ADHD profile from behaviour** and then matches an intervention to it. That is the space Attune enters.
